**18 Abstract**

19 With the aim of optimizing the cloning of novel genes from a genomic pool containing many  
20 previously identified, homologous, genes we designed a redundant exclusion PCR technique. In  
21 RE-PCR a pair of generic amplification primers are combined with additional primers that are  
22 designed to specifically bind to redundant, unwanted genes that are a subset of those copied by the  
23 amplification primers. During RE-PCR the specific primer blocks amplification of the full length  
24 redundant gene. Using this method we managed to clone a number of *cry8* or *cry9* toxin genes  
25 from a pool of *Bacillus thuringiensis* genomic DNA while excluding amplicons for *cry9Da*,  
26 *cry9Ea* and *cry9Eb*. The method proved very efficient at increasing the number of rare genes in  
27 the resulting library. One such rare, and novel, *cry8*-like gene was expressed and the encoded  
28 toxin was shown to be toxic to *Anomala corpulenta*.

**29 Importance**

30 Protein toxins from the bacterium *Bacillus thuringiensis* are being increasingly used as  
31 biopesticides against a wide range of insect pests, yet the search for new or improved toxins is  
32 becoming more difficult as traditional methods for gene discovery routinely isolate previously  
33 identified clones. This paper describes an approach that we have developed to increase the success  
34 rate for novel toxin gene identification through reducing or eliminating the cloning of previously  
35 characterized genes.

## 36 Introduction

37 As a result of the proteinaceous insecticidal toxins produced by *Bacillus thuringiensis* (Bt)  
38 this bacterium has become a commercially successful biopesticide [1]. Products based on Bt  
39 include formulations of the bacterium itself or the toxin expressed in an alternative host – in  
40 particular genetically modified crops [2]. Despite the increasing use of these products there  
41 remains a need to discover new toxins with desirable properties - such properties include an  
42 increased activity against a given target, activity against a new target pest or the ability to control a  
43 pest that has developed resistance to an existing toxin. A number of different approaches can be  
44 used to identify novel toxins, the traditional one being to screen strains for a desired activity and  
45 then isolate the active ingredient. In recent times molecular approaches have been increasingly  
46 used including genome sequencing [3] and PCR techniques. The latter rely on there being  
47 conserved regions present in toxin gene families as well as the more variable regions that give  
48 toxins their individual characteristics [4]. Improved PCR procedures have allowed the successful  
49 cloning of Bt toxin genes from complex DNA mixtures prepared from pooled samples [5, 6]. A  
50 problem with this sort of approach however is the high ratio of known or undesired toxin genes in  
51 libraries made from these pooled samples which has made the discovery of new genes  
52 increasingly difficult.

53 *B. thuringiensis* Cry8 and Cry9 proteins have significantly different insecticidal spectra  
54 despite phylogenetic analyses indicating that they share high sequence similarity in domains I and  
55 II [7, 8]. Cry8 proteins are toxic to Coleopteran insects while Cry9s have high activity to  
56 Lepidopteran insects [9-12], both are valuable toxins for insect pest management. This paper  
57 describes a procedure developed to analyse *cry8* and *cry9* genes in a DNA pool prepared from

2000 Bt strains and used to efficiently clone novel isolates.

## Materials and methods

Bacterial strains, plasmids, and growth conditions

Bt stains were isolated from soil samples in China as described previously [6]. *E. coli* DH5 $\alpha$  was used for standard transformations, whilst *E. coli* SCS110 (RpsL [strr], thr, leu, endA, thi-1, lacY, galK, galT, ara, tonA, tsx, dam, dcm, upE44, D [lac-proAB] [F0 traD36 proAB lacIqZDM15]) was used to produce non-methylated plasmid DNA for transformation of HD73<sup>-</sup>, a crystal-negative mutant strain of Bt.

The cloning vector pEB was constructed by inserting the pETblue-2 expression region into the *Styl*-*Bgl*III sites of pET-21b. Plasmid pSTK containing the *cry3Aa* promoter and STAB-SD sequence was constructed by Wang et al. [13] and used to express *cry* genes in HD73<sup>-</sup>.

*E. coli* was incubated at 37°C in LB medium (1% NaCl, 1% tryptone, and 0.5% yeast extract), and Bt strains were grown at 30°C on LB agar (1% NaCl, 1% tryptone, 0.5% yeast extract and 1.3%-1.5% agar). To select antibiotic-resistant *E. coli* and Bt strains, ampicillin and kanamycin were added to the culture medium at a final concentration of 100  $\mu$ g/ml and 50  $\mu$ g/ml respectively. All of the cultures were incubated in a rotary shaker at 220 rpm.

Identification of *cry8* and *cry9* genes from pooled genomic DNA

Pooled genomic DNA was prepared from 2000 Bt strains as described by Li et al [6] and used as the template for PCR. A pair of universal primers *cry\_F* and *cry\_R* (Table 1) were designed based on an alignment of *cry8* and *cry9* holotype genes and were used to amplify the

78 toxin coding region of these genes. A 50  $\mu$ l PCR mixture contained 100 ng template DNA, 25  $\mu$ l  
79 2 $\times$ PrimeSTAR master mix (TaKaRa, Dalian, China), and 0.2  $\mu$ mol<sup>-1</sup> of each primer. The reaction  
80 consisted of an initial denaturation step of 94°C for 5 min, 30 cycles of 94°C for 1min; 54°C for  
81 1min; 72°C for 2 min 20 s, and final extension step of 72°C for 10 min. The resulting PCR  
82 product was purified using a DNA gel extraction kit (AXYGEN, Hangzhou, China) and ligated  
83 into the *Ecl136II* site of the pEB vector.

84 The *cry9* and *cry8* genes in the pooled DNA were classified by PCR-RFLP analysis. Genes  
85 were amplified from library clones using *cry\_F* and *cry\_R*, digested with *Hinf* I, and then profiled  
86 by 2% agarose gel electrophoresis. Clones with different restriction length fragment  
87 polymorphism (RFLP) profiles were selected for sequencing.

#### 88 Redundant Exclusion PCR

89 Primers RE9Da\_F and RE9Ea/b\_F (Table 2) were designed to specifically hybridize to  
90 *cry9Da*, and to *cry9Ea/cry9Eb* respectively. Test reactions were performed in 20  $\mu$ L total volume  
91 containing 10 ng of *cry9Ea* and *cry9Eb* or *cry9Da*-encoding plasmid DNA, 0.2  $\mu$ molL<sup>-1</sup> primer  
92 RE9Da\_F or RE9Ea/b\_F, 0.2  $\mu$ mol L<sup>-1</sup> of primer *cry\_F* and/or *cry\_R*, and 10  $\mu$ l 2 $\times$ PrimeSTAR  
93 master mix. PCR consisted of an initial denaturation step of 94°C for 5 min, 30 cycles of 94°C  
94 1min; 54°C 1min; 72°C, 2 min 20 s, and a final extension step of 72°C for 10 min.

#### 95 Expression of the *cry8*-like gene

96 To express the truncated *cry8*-like gene in Bt, a seamless assembly cloning method was used  
97 to fuse the truncated gene to DNA encoding the Cry8Ea C-terminal coding region. The primers  
98 designed to amplify these two sections, with appropriate overlaps, are listed in Table 3. A 10  $\mu$ L

99 reaction mix containing 20 ng pSTK plasmid (linearized with *Bam*HI+*Sal*II), 30 ng each of the  
100 PCR products and 5  $\mu$ L 2 $\times$ Assembly Master Mix (Seamless Assembly Cloning kit, CloneSmarter,  
101 USA) was incubated at 50°C for 10 min. After transformation of *E. coli* DH5 $\alpha$  the resulting hybrid  
102 (hycry8) was sequenced using an automated DNA sequencer (ABI-3730XL, USA). The  
103 recombinant plasmid, isolated from *E.coli*, was used to transform SCS110 prior to introduction  
104 into Bt strain HD73<sup>-</sup> by electroporation. A single transformant was selected from LB plates  
105 containing kanamycin (50 g/ml) and incubated until sporulation at 30°C. The spore-crystal  
106 mixture was washed and re-suspended in sterile distilled water, and the suspension was examined  
107 by microscopy and SDS-PAGE analysis according to Shu et al [14]. For proteolytic activation the  
108 toxin crystals were solubilized in 50mM Na<sub>2</sub>CO<sub>3</sub> pH10 and then treated with chymotrypsin (10:1  
109 w/w) in PBS and incubated at 37°C for 2 h.

#### 110 Insect bioassay

111 The insecticidal activity of spore-crystal mix from the recombinant Bt strain was tested  
112 against larvae of 15-day-old *Anomala corpulenta*, 5-day-old *Holotrichia parallela*, and 5-day-old  
113 *Holotrichia oblita*. The bioassay diet for these scarab larvae was prepared as described by Yu et al  
114 [15]. For initial screening, we used a concentration of  $1.0 \times 10^8$  colony forming units (CFU) g<sup>-1</sup>soil.  
115 Further assays were performed with samples showing toxicity to any of the pests in order to  
116 determine LC<sub>50</sub> values. Bioassays were repeated at least twice, and LC<sub>50</sub> values were calculated  
117 using probit analysis.

118

## 119 Results

### 120 Identification of *cry8* and *cry9* genes from pooled genomic DNA

121 A library of 2.1 kb PCR products encoding the active portion of *cry8/9* toxin genes (Fig.1A  
122 lane1), produced from the pooled genomic DNA using primers *cry\_F* and *cry\_R*, was created and  
123 subjected to PCR-RFLP analysis. Two hundred clones were tested and four distinct profile types  
124 were detected (Fig.1B lane1-4). Representatives of these were sequenced and this indicated that  
125 the four profiles belonged to *cry9Da* (100% identity to *cry9Da4*, accession number: GQ249297.1),  
126 *cry9Ea* (99% identity to *cry9Ea9*, accession number: JN651495.1), *cry9Eb* (99% identity to  
127 *cry9Eb2*, accession number: GQ249298.1) and a new *cry8*-like (86% identity to *cry8Ab1*,  
128 accession number: EU044830.1). Figure 2 (solid bars) shows the relative frequency of these four  
129 profiles, 70% of the clones matched the *cry9Ea* profile while 5% matched *cry8*-like.

### 130 Redundant Exclusion primer PCR

131 To exclude known genes from the library we relied on the fact that the high fidelity  
132 polymerase that we used in our PCR reactions (PrimeSTAR GXL) lacks a 5'-3' exonuclease  
133 activity and so polymerization can be halted by the presence of a bound oligonucleotide. We  
134 designed primers that would specifically, and tightly, bind to particular *cry8/9* genes and thus  
135 prevent amplification of the full PCR product by the primers. The primers RE9Da\_F and  
136 RE9Ea/b\_F (Tables 2 and 4) were designed to hybridize to variable regions in domain II of  
137 *cry9Da* and *cry9Ea/9Eb* respectively. A number of PCRs were run to test these primers. When the  
138 two amplification primers and the two redundant exclusion primers were all included in a  
139 multiplex PCR (Fig1A lane 2) two distinct bands are seen, the 2.1kb band represents the full

length products amplified by cry\_F and cry\_R while the approximately 750 bp band represents the fragment of the gene amplified by RE9Da\_F/RE9Ea/b\_F and cry\_R. The source of this 750 bp band was confirmed in separate reactions involving just an RE primer and cry\_R (Fig 1A lanes 3 and 4). To confirm that the RE primers could block amplification of the corresponding gene pairs of reactions were performed using specific genes as templates. Figure 1A lanes 5-8 show that amplification of the full length gene is completely (*cry9Da* lane 8) or mostly (*cry9Ea/b* lane 6) inhibited by the appropriate RE primer.

A new library was created from the 2.1kb PCR product produced using cry\_F and cry\_R from pooled DNA but this time including the RE primers in the amplification reaction. A total of 200 clones were analyzed by PCR-RFLP and this time five different profiles were obtained (Fig.1B lanes 3-7). Two of these profiles (*cry9Ea* and *cry8*-like) were the same as previously identified while the other three corresponded to *cry8Fa* (99% identity to *cry8Fa2*, accession number HQ174208.1), *cry8Ab*-like (99% identity to *cry8Ab1*-like, accession number: JF521572.1) and *cry8Ea* (99% identity to *cry8Ea1*, accession number: AY329081.1). Although the *cry9Ea* profile was detected despite the presence of the corresponding RE primer its frequency had dropped dramatically (Figure 2 open bars). The *cry9Da* and *cry9Eb* profiles had successfully been excluded. In contrast the frequency of the *cry8*-like profile rose significantly.

Expression of the novel *cry8*-like gene

The cry\_F and cry\_R primers were designed to amplify the active toxin portion of the *cry8/9* genes but not the region encoding the C-terminal crystallization domain [4]. To express a complete toxin we added this C-terminal region from a homologous gene, *cry8Ea*. Figure 3 shows the sequence of the Cry8-like toxin and the resulting hybrid (hyCry8). The hybrid gene was

sub-cloned into pSTK and introduced into HD73<sup>-</sup> for expression. The hyCry8 protein expressed well in this host (Fig.4C lane 2) and accumulated as spherical crystals (Fig.4B). When the protoxin was treated with chymotrypsin (Fig.4C lane 3), a 60 kDa protein was obtained as expected [16].

#### Insect bioassay

To evaluate the toxicity of the hybrid protein, spore/crystal mix of the recombinant Bt strain was tested for insecticidal activity on larvae of 15-day stage *A.corpulenta*, 5-day stage *H.parallela*, and 5-day stage *H.oblita*. At a concentration of  $1.0 \times 10^8$  CFU g<sup>-1</sup> soil the parent strain HD73<sup>-</sup> had no insecticidal activity against any of the three bioassayed insects. The strain expressing the hybrid was shown to be toxic to *A.corpulenta* larvae (Fig.5) but not to *H.parallela* or *H.oblita*.

#### Discussion

In recent years many research projects have focused on cloning desired genes from complex DNA samples (metagenomic or pooled DNA) [5, 6, 17-19]. In such samples the distribution of gene homologues can be unequal and it can be a difficult task to isolate rare forms. Here we have demonstrated the use of redundant exclusion PCR to remove unwanted homologues from a gene pool and thus increase the frequency of rare forms in an amplicon library.

Bt is an insect pathogen which during sporulation produces insecticidal proteins that accumulate in the mother cell and form intracellular parasporal crystals [1, 20]. These crystals contain toxins, encoded by *cry* genes, which are noted for their specific insecticidal activity. Cry proteins have been expressed in crops to control agricultural pests [21, 22]. Due to their commercial value much research has focused on toxin gene discovery and here we have demonstrated the use of an RE-PCR based method that can identify new and rare *cry* gene

183 homologues from a genomic DNA pool and identified a novel toxin with activity against an  
184 economically important pest. The method relies on us being able to identify unique regions in  
185 redundant genes and would therefore exclude any otherwise novel genes that happened to share  
186 that region. Nonetheless we have demonstrated that the principle works well and alternative RE  
187 primers can always be designed in an attempt to overcome this potential limitation. The fact that  
188 some *cry9Ea* profiles could still be detected may represent the fact that this process is not 100%  
189 efficient and so there can be some background, which will be particularly noticeable for high  
190 abundance genes. Alternatively polymorphisms in the RE primer region could allow amplification  
191 of these variants.

192       The toxin that we identified by this method is closely related to other Cry8 toxins,  
193 comparison of the active toxin region with all toxins in the nomenclature reveals that the closest  
194 match is to Cry8Ab1 with 79% identity. This level of identity is sufficient to consider the toxin  
195 novel - studies have shown that just a few amino acid differences in a toxin can not only determine  
196 whether or not it is toxic, but also to which insect it has toxicity [23]. This conclusion is supported  
197 by our bioassay data: the variant that we have isolated shows activity to *A. corpulenta* but not to *H.*  
198 *oblita* or *H. parallela*. This contrasts with Cry8N which showed activity against the latter insect  
199 but not the former two [24], with Cry8Ga which has activity against the two *Holotrichia* species  
200 but not *A. corpulenta* [12], Cry8Ab with activity against the two *Holotrichia* species [25] and with  
201 Cry8Fa and another Cry8-like protein that have activity against none or all of these three species  
202 respectively [10, 11]. Thus on both sequence and insect specificity levels this newly described  
203 toxin has novel attributes which have potential not only for the control of these insects but also in  
204 the understanding of specificity determination. It should be noted that our bioassays were

205 conducted on a hybrid toxin in which the C-terminal region was provided by another toxin. While  
206 the C-terminal region of the larger Cry toxins is known to be important for toxin  
207 expression/packaging [26] and may influence toxicity [27] there is no convincing evidence that it  
208 influences specificity and thus we believe that it is reasonable to attribute the observed activity to  
209 the newly cloned portion of the toxin.

210 In conclusion, the RE-PCR based approach developed in this paper was able to effectively  
211 exclude undesired homologue genes but clone low frequency genes from a complex DNA sample.  
212 It is particularly applicable to families of homologous genes where there are known areas with  
213 variation that can be used for the design of the RE primers, the method should be suitable for other  
214 samples such as metagenomic DNA.

#### 215 Ethical Statement

216 The authors declare that they have no competing interests; the manuscript does not contain  
217 experiments using mammals and does not contain studies on humans.
